Lattice 2014

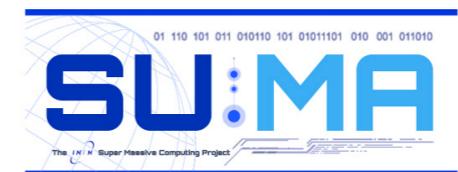

June 23-28, Columbia University, New York, USA

Outline

- **Introduction**
- **Lattice setup and numerical simulation**
- **Numerical results**
- **Conclusions**

based on P. Cea, L.C., A. Papa, Phys.Rev. D89 (2014) 074512 (arXiv:1403.0821)

This work has been partially supported by the INFN SUMA project.

Simulations have been performed on BlueGene/Q at CINECA (CINECA-INFN agreement under INFN project PI12), on the BC²S cluster in Bari and on the CSNIV Zefiro cluster in Pisa.

- The QCD (pseudo)critical line can be parameterized by a lowest order Taylor expansion in the baryon chemical potential:

$$\frac{T(\mu_B)}{T_c(0)} = 1 - \kappa \left(\frac{\mu_B}{T(\mu_B)} \right)^2$$

- Lattice QCD can be used to locate the QCD (pseudo)critical line.

BUT the “*sign problem*” prevents us to do simulations at **real** nonzero baryon chemical potential.

- Possible way out: *analytic continuation* from an *imaginary* chemical potential (other methods: reweighting from the ensemble at $\mu_B=0$, the Taylor expansion method, the canonical approach, the density of states method).
- The aim of this work is to give a first estimate of the (pseudo)critical line by the method of analytic continuation of (2+1) flavor QCD using the HISQ/tree action.

Lattice setup and numerical simulation

- *Highly improved staggered quark action* with *tree level improved Symanzik gauge action (HISQ/tree)* with 2+1 flavors as implemented in the **MILC** code (<http://www.physics.utah.edu/~detar/milc/>).
- We work on a *line of constant physics (LCP)* determined (*) by fixing the *strange quark mass* to its physical value m_s at each value of the gauge coupling β . The *light-quark mass* has been fixed at $m_l = m_s/20$.
(* as determined in A. Bazavov et al (HotQCD Collaboration), PRD 85, 054503 (2012))
- In the present study we assign the same quark chemical potential to the three quark species:
$$\mu_l = \mu_s \equiv \mu = \mu_B/3$$
- To perform numerical simulations we used the **MILC** code suitably modified in order to introduce an imaginary quark chemical potential $\mu = \mu_B/3$.
That has been done by multiplying *all forward and backward temporal links* entering the discretized Dirac operator by $\exp(i a \mu)$ and $\exp(-i a \mu)$, respectively.
- All simulations make use of the rational hybrid Monte Carlo (RHMC) algorithm.
The length of each RHMC trajectory has been set to 1.0 in molecular dynamics time units.

- We have simulated **QCD at finite temperature and imaginary quark chemical potential** on lattices of size **$16^3 \times 6$, $24^3 \times 6$, $32^3 \times 8$** (to check for finite size effects and for finite cutoff effects)
- We have typically discarded not less than 1000 trajectories for each run and have collected from 4000 to 8000 trajectories for measurements
- To determine the (pseudo)critical line we have to estimate the (pseudo)critical coupling

$$\beta_c(\mu^2)$$

in correspondence of a given value of the imaginary quark chemical potential.

- We considered the following values for the quark chemical potential:

Lattice	$\mu/(\pi T)$
$16^3 \times 6$	0.
	$0.15i$
	$0.2i$
	$0.25i$
$24^3 \times 6$	0.
	$0.2i$
$32^3 \times 8$	0.
	$0.2i$

Numerical results

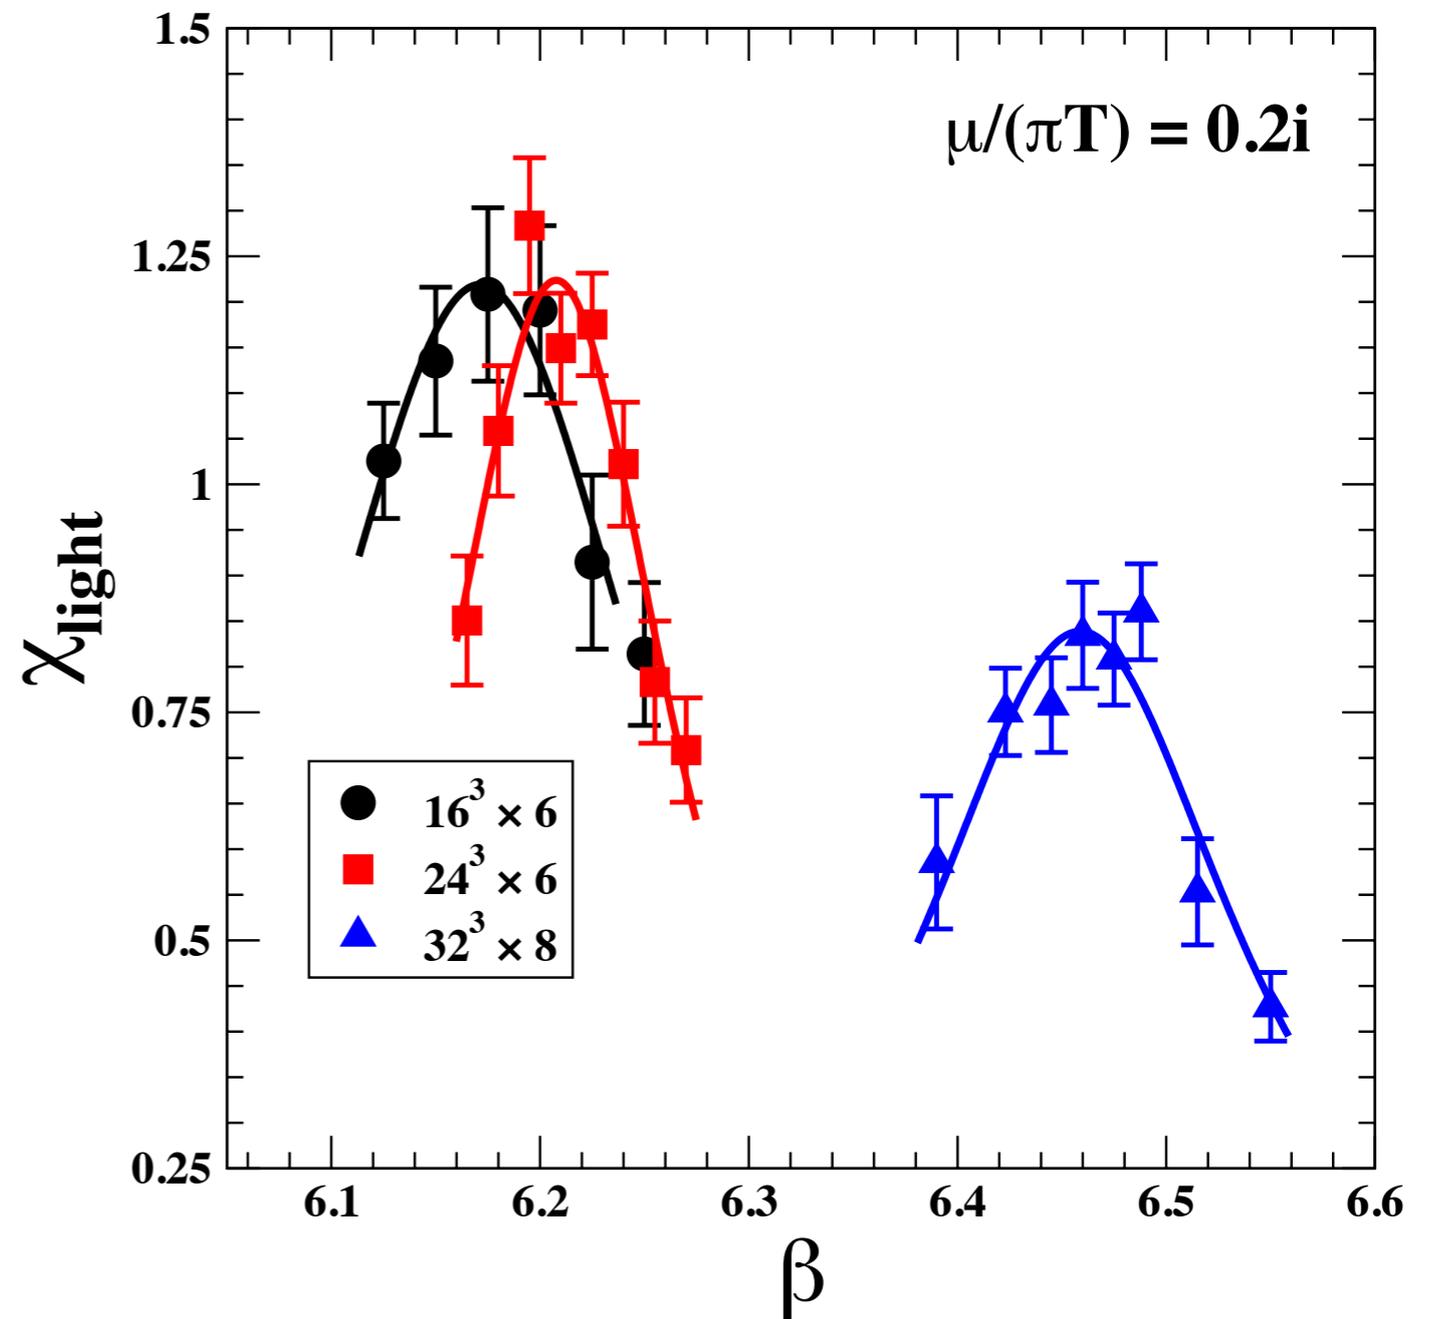

The (pseudo)critical line $\beta_c(\mu^2)$ has been determined as the value for which the **disconnected susceptibility of the light quark chiral condensate** exhibits a peak

$$\chi_{q,disc} = \frac{n_f^2}{16N_\sigma^3 N_\tau} \left\{ \langle (\text{Tr} D_q^{-1})^2 \rangle - \langle \text{Tr} D_q^{-1} \rangle^2 \right\}$$

Numerical results

The (pseudo)critical line $\beta_c(\mu^2)$ has been determined as the value for which the disconnected susceptibility of the light quark chiral condensate exhibits a peak

$$\chi_{q,disc} = \frac{n_f^2}{16N_\sigma^3 N_\tau} \left\{ \langle (\text{Tr} D_q^{-1})^2 \rangle - \langle \text{Tr} D_q^{-1} \rangle^2 \right\}$$

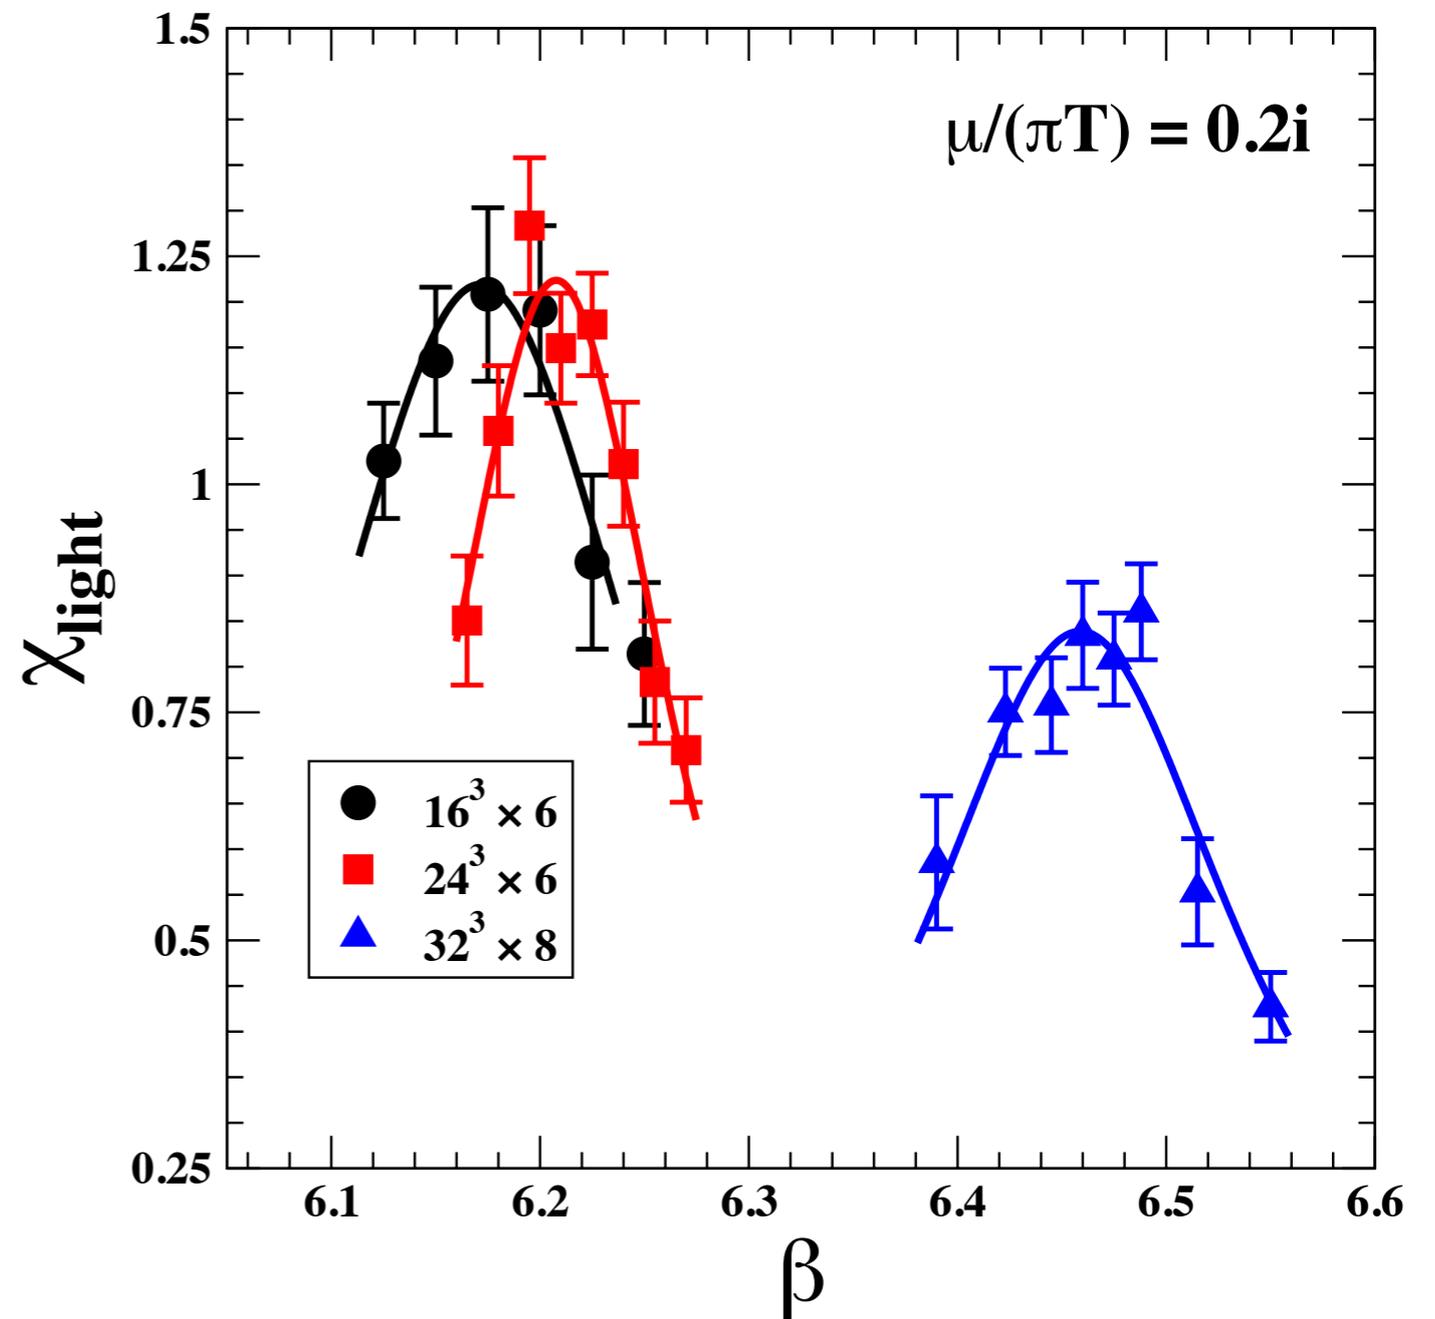

Numerical results

The (pseudo)critical line $\beta_c(\mu^2)$ has been determined as the value for which the **disconnected susceptibility of the light quark chiral condensate** exhibits a peak

To localize the peak, a Lorentzian fit has been used:

$$\frac{a_1}{1 + a_2(\beta - \beta_c)^2}$$

$$\chi_{q,disc} = \frac{n_f^2}{16N_\sigma^3 N_\tau} \left\{ \langle (\text{Tr} D_q^{-1})^2 \rangle - \langle \text{Tr} D_q^{-1} \rangle^2 \right\}$$

Numerical results

The (pseudo)critical line $\beta_c(\mu^2)$ has been determined as the value for which the **disconnected susceptibility of the light quark chiral condensate** exhibits a peak

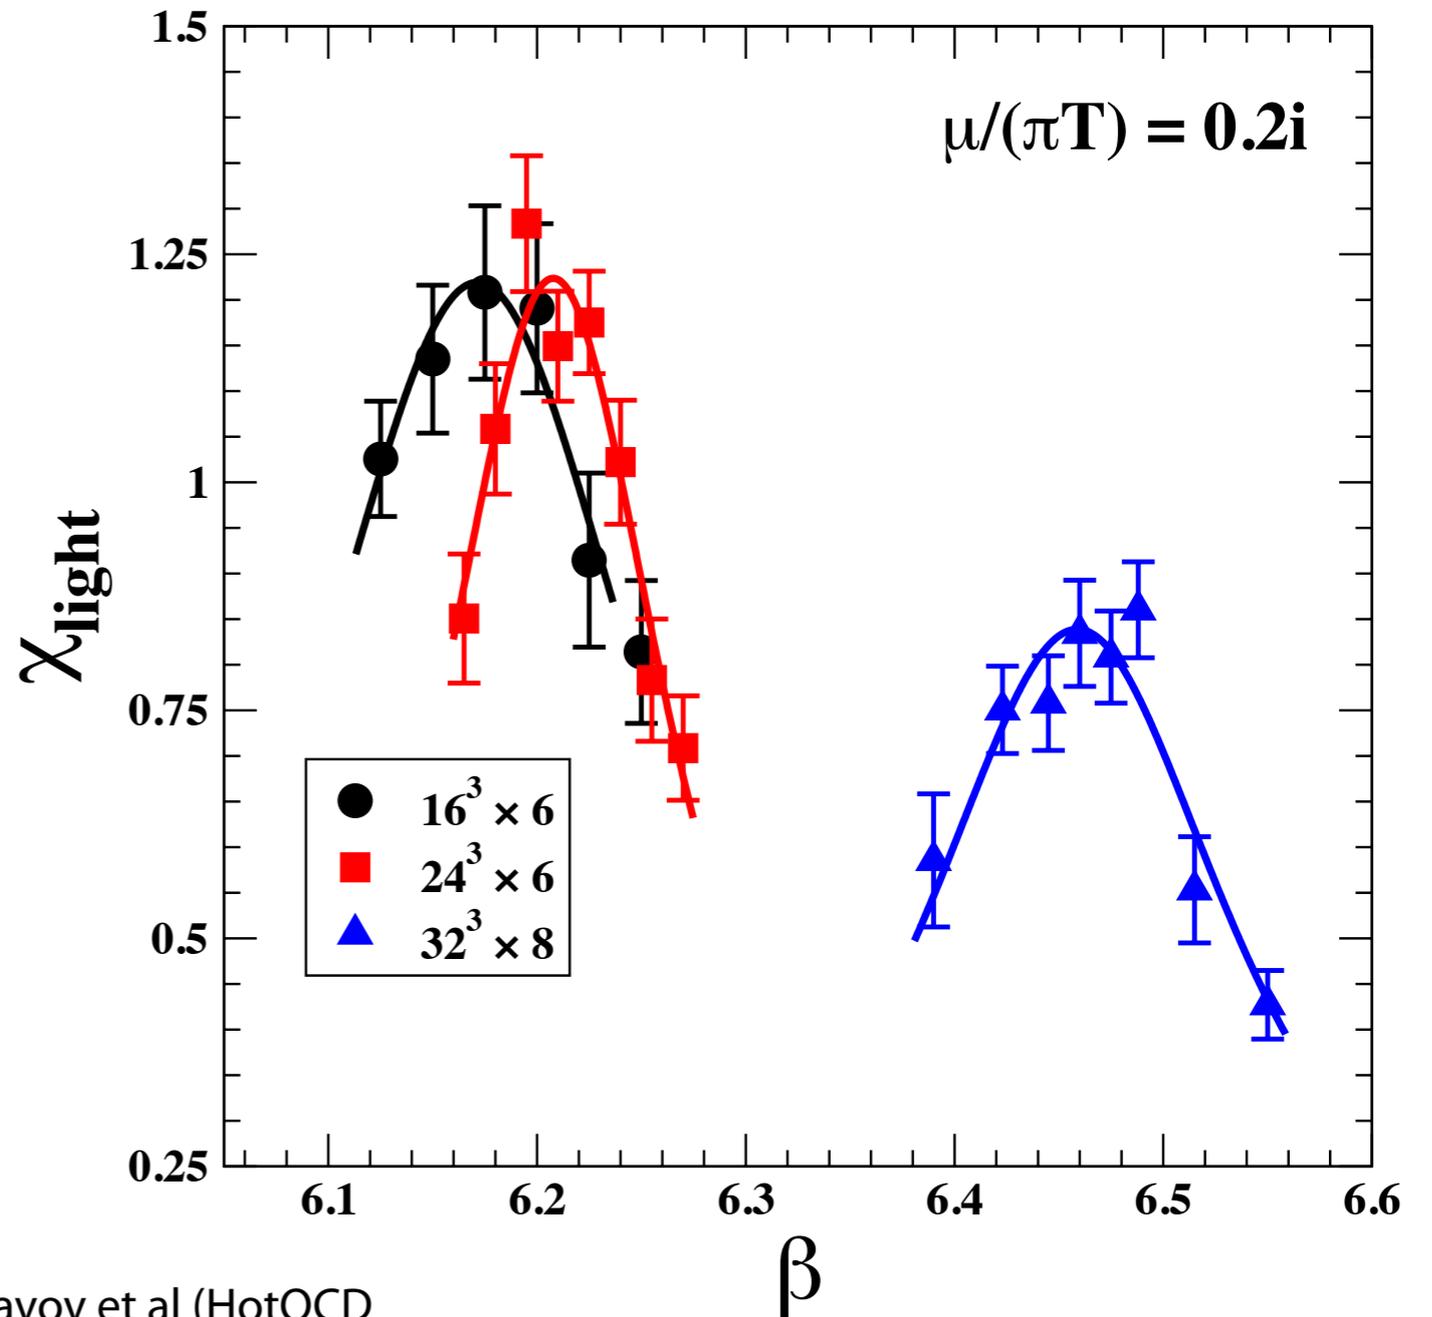

To localize the peak, a Lorentzian fit has been used:

$$\frac{a_1}{1 + a_2(\beta - \beta_c)^2}$$

Lattice	$\mu/(\pi T)$	β_c
$16^3 \times 6$	0.	6.102(8)
	$0.15i$	6.147(10)
	$0.2i$	6.171(12)
	$0.25i$	6.193(14)
$24^3 \times 6$	0.	6.148(8) (*)
	$0.2i$	6.208(5)
$32^3 \times 8$	0.	6.392(5) (*)
	$0.2i$	6.459(9)

(*) fit to data taken from Table X and Table XI of A.Bazavov et al (HotQCD Collaboration) arXiv:1111.1710 Phys. Rev. D 85, 054503 (2012)

$$\chi_{q,disc} = \frac{n_f^2}{16N_\sigma^3 N_\tau} \left\{ \langle (\text{Tr} D_q^{-1})^2 \rangle - \langle \text{Tr} D_q^{-1} \rangle^2 \right\}$$

In order to check our estimate for the peaks, we also locate the peaks in the **renormalized susceptibility**

$$\frac{1}{Z_m^2} \frac{\chi_{\text{light}}}{T^2} \quad Z_m = \frac{m_{\text{light}}(\beta)}{m_{\text{light}}(\beta^*)} \quad T = \frac{1}{a(\beta)L_t}$$

$$\frac{r_1}{a(\beta^*)} = 2.37$$

To set the lattice spacing (*)

$$\frac{a}{r_1}(\beta)_{m_l=0.05m_s} = \frac{c_0 f(\beta) + c_2(10/\beta) f^3(\beta)}{1 + d_2(10/\beta) f^2(\beta)}$$

$$r_1 = 0.3106 \text{ fm}$$

$$c_0 = 44.06$$

$$c_2 = 272102$$

$$d_2 = 4281$$

$$f(\beta) = (b_0(10/\beta))^{-b_1/(2b_0^2)} \exp(-\beta/(20b_0))$$

b_0, b_1 coefficients of the universal two-loop beta function

or

$$a f_K(\beta)_{m_l=0.05m_s} = \frac{c_0^K f(\beta) + c_2^K(10/\beta) f^3(\beta)}{1 + d_2^K(10/\beta) f^2(\beta)}$$

$$r_1 f_K = 0.1738$$

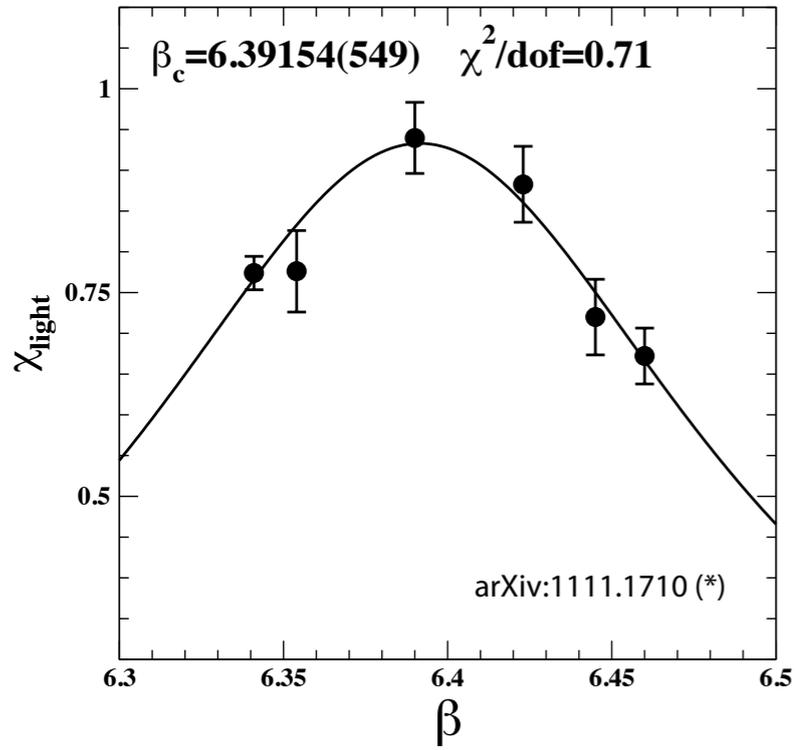

$$c_0^K = 7.66$$

$$c_2^K = 32911$$

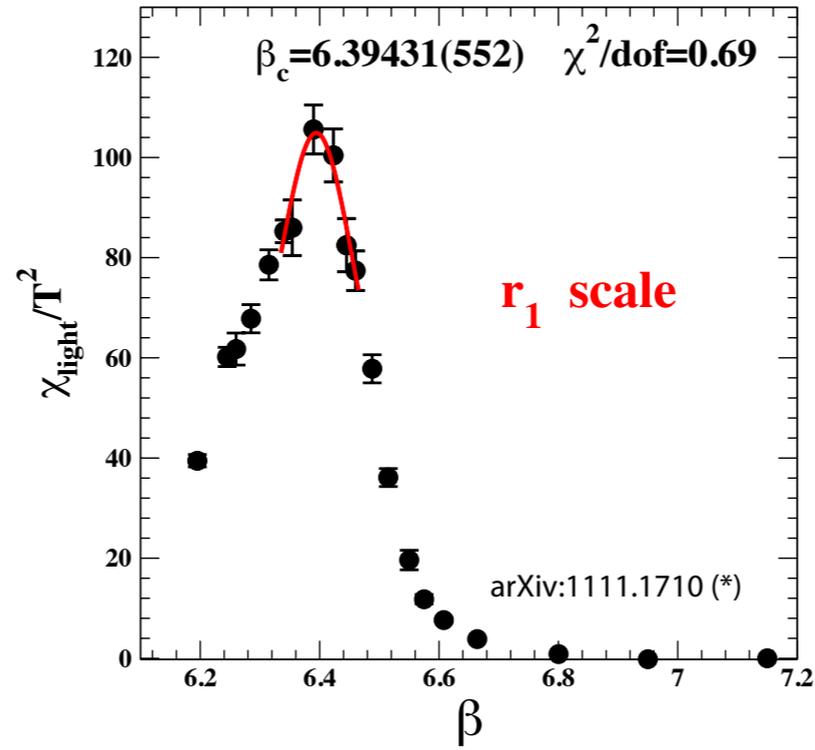

$$d_2^K = 2388$$

The critical temperature vs. imaginary quark chemical potential

Lattice	$\mu/(\pi T)$	β_c	$T_c(\mu)/T_c(0)$
$16^3 \times 6$	0.	6.102(8)	1.000
	$0.15i$	6.147(10)	1.045(13)
	$0.2i$	6.171(12)	1.070(15)
	$0.25i$	6.193(14)	1.093(17)
$24^3 \times 6$	0.	6.148(8)	1.000
	$0.2i$	6.208(5)	1.060(10)
$32^3 \times 8$	0.	6.392(5)	1.000
	$0.2i$	6.459(9)	1.068(11)

$$\frac{T_c(\mu)}{T_c(0)} = \frac{a(\beta_c(0))}{a(\beta_c(\mu))}$$

$$\frac{a}{r_1}(\beta)_{m_l=0.05m_s} = \frac{c_0 f(\beta) + c_2(10/\beta) f^3(\beta)}{1 + d_2(10/\beta) f^2(\beta)}$$

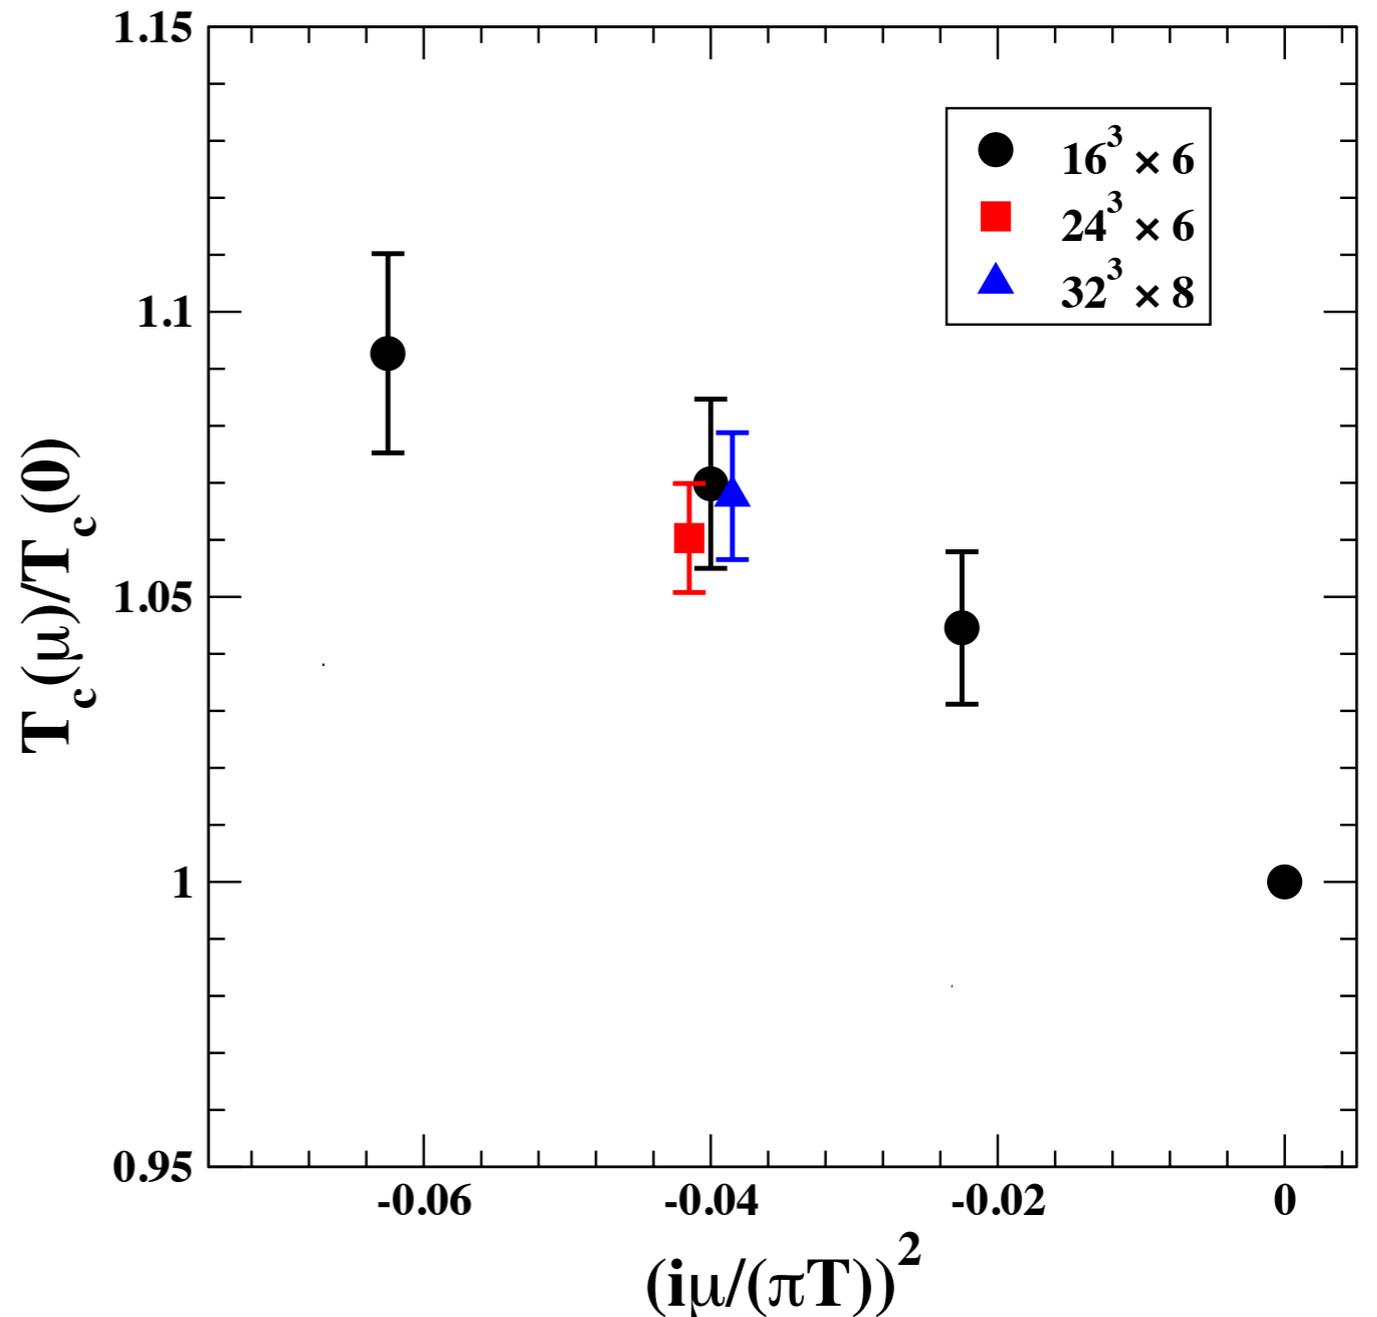

$$f(\beta) = (b_0(10/\beta))^{-b_1/(2b_0^2)} \exp(-\beta/(20b_0))$$

$$r_1 = 0.3106 \text{ fm}$$

$$c_0 = 44.06$$

$$c_2 = 272102$$

$$d_2 = 4281$$

Linear fit (in μ^2) to the data

$$\frac{T_c(\mu)}{T_c(0)} = 1 + R_q \left(\frac{i\mu}{\pi T_c(\mu)} \right)^2$$

for the $16^3 \times 6$ lattice:

$$R_q = -1.63(22)$$

$$\chi^2/\text{d.o.f.} = 0.39$$

curvature of the (pseudo)critical line:

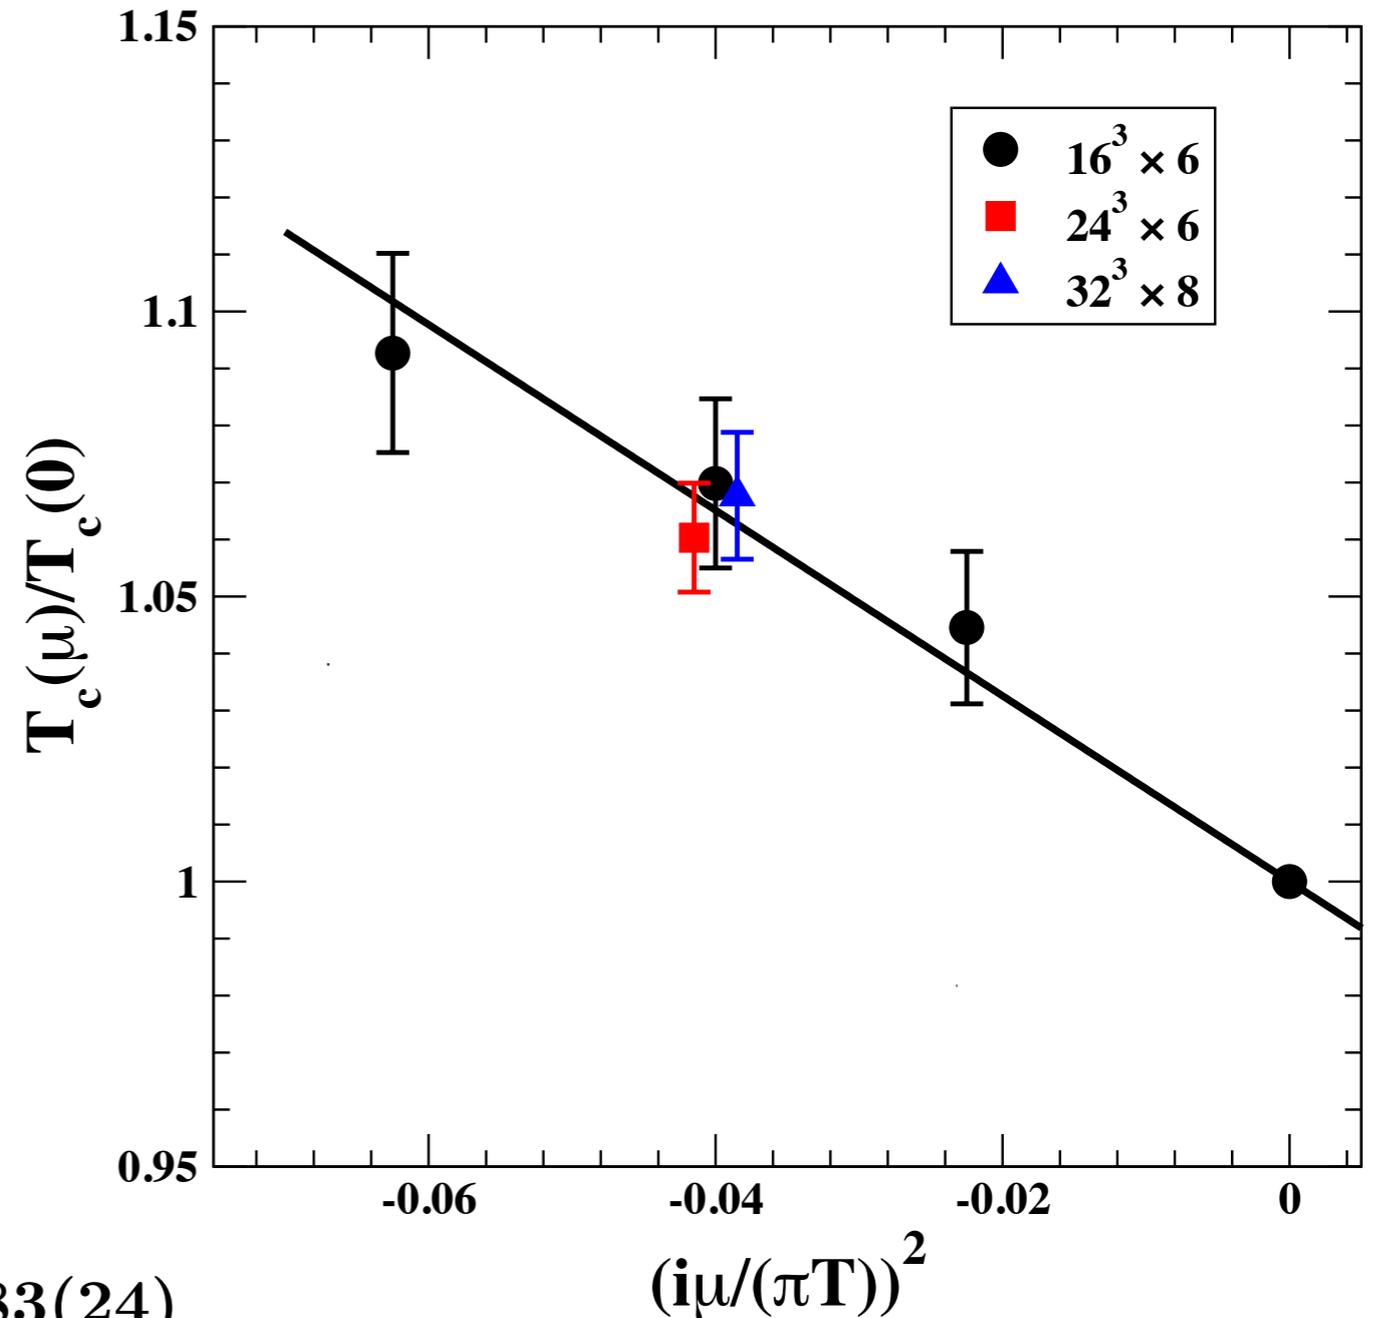

$$\kappa = -\frac{R_q}{(9\pi^2)} = 0.0183(24)$$

Assuming that linearity still holds on the other lattices:

$$R_q(16^3 \times 6) = -1.63(22), \quad \kappa = 0.0183(24)$$

$$R_q(24^3 \times 6) = -1.51(25), \quad \kappa = 0.0170(28)$$

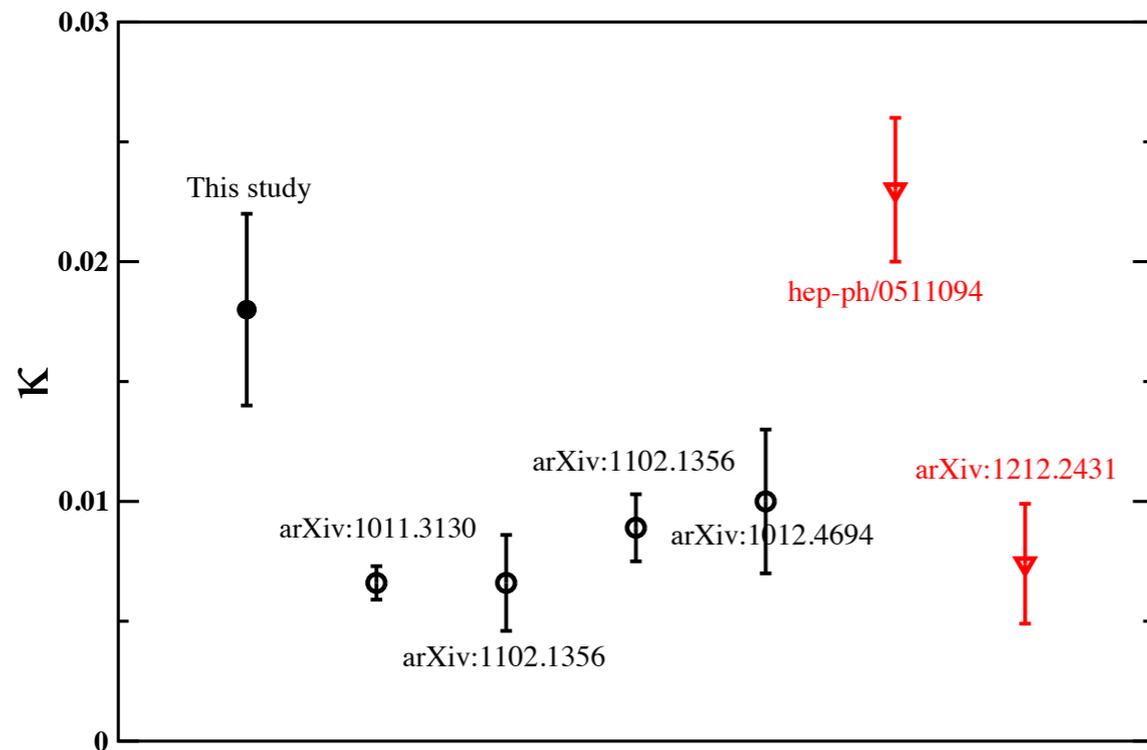

$$R_q(32^3 \times 8) = -1.70(29), \quad \kappa = 0.0190(32)$$

our estimate:

$$\kappa = 0.018(4)$$

Comparison with other results for the curvature κ

freeze-out curvature, analysis based on the standard statistical hadronization model

arXiv:1212.2341 F. Becattini, M. Bleicher, Th. Kollegger, T. Schuster, Jan Steinheimer, and Reinhard Stock, Phys.Rev.Lett. 111 (2013) 082302

freeze-out curvature, revised analysis

Estimate of the (pseudo)critical line

From our estimate of the curvature

$$\kappa = 0.018(4)$$

and

$$T_c(\mu_B) = a - b\mu_B^2$$

$$a = T_c(0)$$

$$b = \frac{\kappa}{T_c(0)}$$

$$T_c(0) = 154(9) \text{ MeV} \quad (*)$$

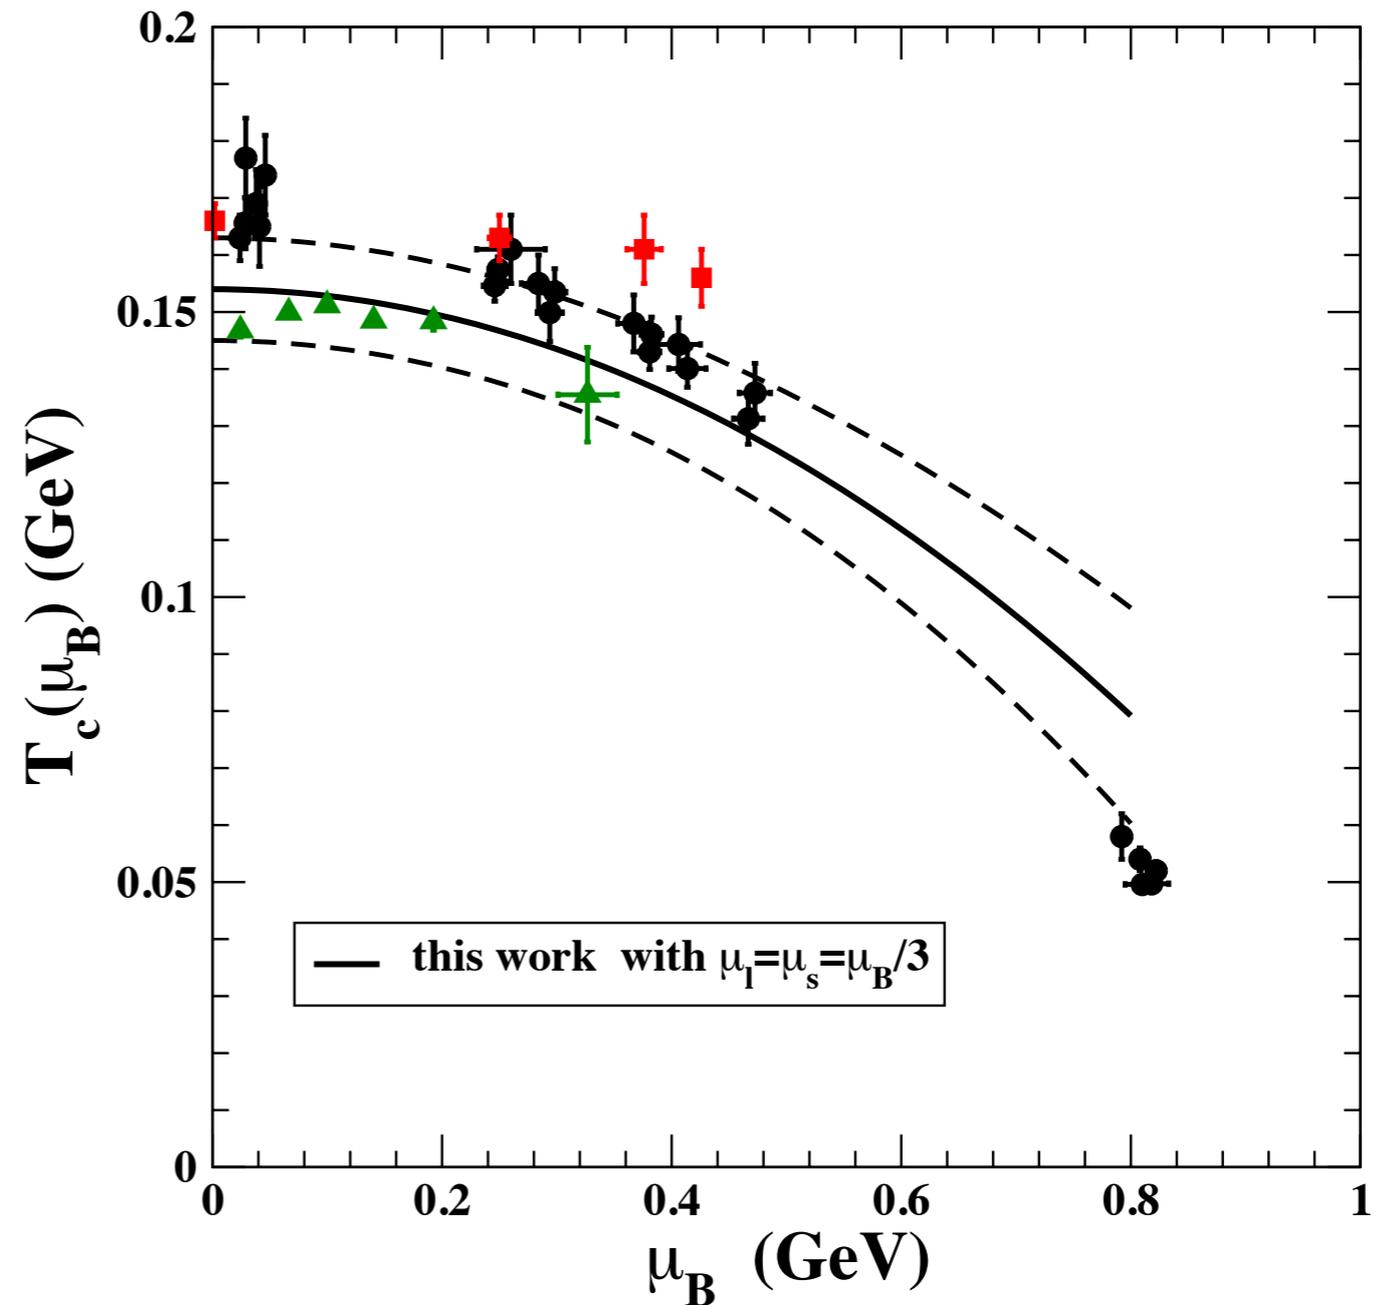

we get:

$$b = 0.117(27) \text{ GeV}^{-1}$$

to be compared with:

$$b = 0.139(16) \text{ GeV}^{-1}$$

Summary and Conclusions

- We have determined the curvature κ of the QCD (pseudo)critical line with 2+1 flavors and $m_l/m_s = 1/20$ and the HISQ/tree action, with $\mu=\mu_l=\mu_s$
- Our determination $\kappa=0.018(4)$ is larger than previous lattice determinations and seems to be in better agreement with the freeze-out curvature based on the standard statistical hadronization model.
- Possible reasons for the disagreement with previous lattice determinations:
 - different methods to avoid the sign problem (analytic continuation in our work)
 - different lattice discretizations (HISQ/tree action in our work)
 - different setup of quark chemical potentials ($\mu=\mu_l=\mu_s$ in our work)
- **To do:**
 - other values of $\mu/(\pi T)$ for $24^3 \times 6$ and $32^3 \times 8$ lattices to check linearity in μ^2
 - extrapolation to the continuum limit
 - extension to the physical value of the light to strange mass ratio $m_l/m_s = 1/28$
 - study the possible effect of varying the strange quark chemical potential
